Q: Implementing a queue in C++ using vectors and iterators I would like to use a queue implemented with a vector of shared\_ptr. As for a random access queue, I want to use both a push\_front and push\_back function of the queue so I could write queue\_a.push\_back(a); queue\_a.push\_back(b); I am using c++11. So I started thinking about the following queue implementation: // define a class type struct T { // define a default constructor for this queue. // This means it will be filled with values // when it is created. T() : count(0), size(0) { } // initialize the queue members. void init(int size) { queue.reserve(size); count = size; size = 0; } // parameters can be changed. void init(int capacity) { // this is a queue that could be accessed by the user and // overpopulated with random values. queue.reserve(capacity); capacity = 0; } // This is the queue class that is used to define the // queue. I need it to be a

---

vector of shared\_ptr, so // that I could use push\_back and push\_front. vector> queue; // This is the count value. A queue can be 3da54e8ca3
