In the past, the ventilation of private, usually single family dwellings, has been accomplished by installing an air conditioning system and a heating system, installed individually, in each residence. The air conditioner system provides for the heating and cooling of the air in the living space, while the heating system, when used, is used to heat the air in the living space. In the summer, an air conditioner system is used to cool the air in the living space, and in the winter, a heating system is used to heat the air in the living space. For the most part, the prior art air conditioner systems were the gaseous compression type, with separate indoor and outdoor compressors, and an air distribution unit in the form of a conditioned air duct and an outdoor air supply duct. The air conditioning unit was usually located in the attic of the structure. Generally, the system was controlled by an outdoor temperature-sensing device and an indoor temperature-sensing device located in the living space and connected by a thermostat to the outdoor compressor. The cooling effect of the compressor was controlled, either by increasing or decreasing the amount of refrigerant fluid flowing through the condenser coil and into the compressor. As the outdoor temperature decreased, the outdoor compressor would increase the suction pressure of the compressor to increase the rate at which refrigerant fluid was compressed into a gaseous state. The compressor ran longer, and the compressor would decrease the amount of condensate that was recycled from the evaporator to the compressor. As the outdoor temperature increased, the compressor would decrease the suction pressure to decrease the rate at which refrigerant fluid was compressed into a gaseous state. The compressor ran less, and the compressor would increase the amount of condensate that was recycled from the evaporator to the compressor. In the prior art air conditioning systems, the outdoor and indoor temperature sensors were generally located at the base or ends of the conditioned air duct to sense the temperature of the air that was being conditioned and distributed within the residence. The thermostat was generally located in the living space and was electrically connected to the outdoor and indoor temperature sensors. The temperature of the air in the conditioned air duct was sensed and measured by the indoor and outdoor temperature sensors. As the temperature of the conditioned air, that is, the air within the conditioned air duct, reached the sensed temperature of the indoor or outdoor temperature sensor, the thermostat was energized and control of the air conditioner system was provided by the ther
